A semiclassical kinetic theory is presented for the fluctuating photon flux emitted by a disordered medium in thermal equilibrium. The kinetic equation is the optical analog of the Boltzmann-Langevin equation for electrons. Vacuum fluctuations of the electromagnetic field provide a new source of fluctuations in the photon flux, over and above the fluctuations due to scattering. The kinetic theory in the diffusion approximation is applied to the super-Poissonian noise due to photon bunching and to the excess noise due to beating of incident radiation with the vacuum fluctuations.

The theory of radiative transfer was developed by Chandrasekhar [1] and Sobolev [2] to describe the scattering and absorption of electromagnetic radiation by interstellar matter. It has become widely used in the study of wave propagation in random media, with applications in medical imaging and seismic exploration [3]. The basic equation of radiative transfer theory is a kinetic equation of the Boltzmann type that is derived from the Maxwell equations by neglecting interference effects [4]. It is a reliable approximation whenever the scattering and absorption lengths are large compared to the wavelength, which applies to all but the most strongly disordered media.

Radiative transfer theory has so far been restricted to classical waves, excluding purely quantum mechanical effects of vacuum fluctuations. This limitation is felt strongly in connection with the recent activity on random lasers [5]. These are amplifying systems in which the feedback is provided by multiple scattering from disorder rather than by mirrors, so that radiative transfer theory is an appropriate level of description. However, while stimulated emission has been incorporated into this approach a long time ago by Letokhov [6], spontaneous emission has not. It is the purpose of our work to remove this limitation, by presenting an extension of the radiative transfer equation that includes vacuum fluctuations and the associated spontaneous emission of radiation.

Our inspiration came from the field of electronic conduction in disordered metals, where the notion of a fluctuating Boltzmann equation (or Boltzmann-Langevin equation) has been developed extensively [7–9], following the original proposal by Kadomtsev [10]. In that context the fluctuations originate from random scattering and they conserve the particle number. This same class of fluctuations exists also in the optical context considered here, but with a different correlator because of the difference between boson and fermion statistics. In addition, the photons have a new class of fluctuations, without particle conservation, originating from random absorption and emission events. Vacuum fluctuations are of the second class. We will extend the radiative transfer theory to include both classes of fluctuations. To demonstrate the validity of our “Boltzmann-Langevin equation for photons,” we solve the problem of the excess noise from vacuum fluctuations in a waveguide geometry, for which an independent solution is known [11]. We then apply it to the unsolved problem of the thermal radiation from a spherical random medium.

The basic quantity of the kinetic theory is the fluctuating distribution function \( f_k(r) \) of the number of photons per unit cell \((2\pi)^{-3}d^3k\) in phase space. (For simplicity, we ignore the polarization dependence.) Conventional radiative transfer theory deals with the mean \( \bar{f}_k(r) \), which we assume to be time independent. It satisfies the Boltzmann equation

\[
\frac{\partial \bar{f}_k}{\partial r} = \sum_{k'} \left[ J_{kk'}(\bar{f}) - J_{k'k}(\bar{f}) \right] + J_{kk}^+(\bar{f}) - \bar{J}_k^-(\bar{f})
\]

(1)

For ease of notation, we write \( \sum_k \) instead of \((2\pi)^{-3} \int d^3k\), and \( \delta_{kq} \) instead of \((2\pi)^3 \delta(k - q) \). The left-hand side is the convection term (with \( c \) the velocity of light in the medium and \( \mathbf{k} \) a unit vector in the direction of the wave number \( k \)). The right-hand side contains gain and loss terms due to scattering, \( J_{kk'}(\bar{f}) = w_{kk'} \bar{f}_k(1 + \bar{f}_{k'}) \), and due to amplification, \( J_{kk}^+(\bar{f}) = w_k^+ (1 + \bar{f}_k) \), and due to absorption \( \bar{J}_k^-(\bar{f}) = w_k^- \bar{f}_k \). The scattering rate \( w_{kk'} = w_{k'k} \) is elastic and symmetric. The absorption and amplification rates \( w_k^\pm \) are isotropic (dependent only on \( k = |k| \)) and related to each other by the requirement that the Bose-Einstein function

\[
f_{eq}(\omega, T) = \left[ \exp(h\omega/k_BT) - 1 \right]^{-1}
\]

is the equilibrium solution of Eq (1) (at frequency \( \omega = ck \) and temperature \( T \)). This requirement fixes the ratio \( w_k^- / w_k^+ = \exp(h\omega/k_BT) \). The temperature \( T \) is positive for an absorbing medium and negative for an amplifying medium such as a laser [12].

We now extend the radiative transfer equation (1) to include the fluctuations \( \delta f = f - \bar{f} \). Following the line of argument that leads to the Boltzmann-Langevin equation.
for electrons [7–10], we propose the kinetic equation

\[
\mathbf{c} \cdot \nabla f = \sum_{k'} [J_{kk'}(f) - J_{kk}(f)]
\]

\[
+ I_k^+(f) - I_k^-(f) + L_k.
\]  

(3)

The argument is that the fluctuating \( \delta / \) is propagated, scattered, absorbed, and amplified in the same way as the mean \( f \), hence the same convection term and the same kernels \( J_{kk'} \) appear in Eqs. (1) and (3). In addition, Eq. (3) contains a stochastic source of photons, consisting of separate contributions from scattering, amplification, and absorption. This Langevin term has zero mean, \( \langle \delta / \rangle = 0 \), and a correlator that follows from the assumption that the elementary stochastic processes \( \delta J_{kk'}, \delta I_k^\pm \) have independent Poisson distributions:

\[
\begin{align*}
\delta J_{kk'}(r, t) \delta J_{qq}(r', t') &= \Delta \delta_{kq} \delta_{kk'} \delta J_{kk}(\bar{f}), \\
\delta I^+_k(r, t) \delta I^-_q(r', t') &= \Delta \delta_{kq} I^+_k(\bar{f}), \\
\delta J_{kk'}(r, t) \delta I^-_q(r', t') &= 0, \\
\delta I^+_k(r, t) \delta I^-_q(r', t') &= 0,
\end{align*}
\]  

(5a–c)

where we have abbreviated \( \Delta = \delta (r - r') \delta (t - t') \).

Substitution into Eq. (4) gives the correlator

\[
L_k(r, t) L_q(r', t') = \Delta \left[ \delta_{kq} \sum_{k'} [J_{kk'}(\bar{f}) + J_{kk}(\bar{f})] - J_{kk}(\bar{f}) - J_{kk}(\bar{f}) + \delta_{kq} I^+_k(\bar{f}) + I^-_k(\bar{f}) \right].
\]  

(6)

Equations (3) and (6) constitute the Boltzmann-Langevin equation for photons.

To gain more insight into this kinetic equation we make the diffusion approximation valid if the mean free path is the shortest length scale in the system (but still large compared to the wavelength). The diffusion approximation consists in an expansion with respect to \( k \) in spherical harmonics, keeping only the first two terms:

\[
f_k = f_0 + k \cdot f_1, \quad L_k = L_0 + k \cdot L_1, \quad \text{where } f_0, f_1, L_0, \text{ and } L_1 \text{ do not depend on the direction } k \text{ of the wave vector, but on its magnitude } k = \omega/c \text{ only.}
\]

The two terms \( f_0 \) and \( f_1 \) determine, respectively, the photon number density \( n = \rho f_0 \) and flux density \( j = j_0 f_1 \), where \( \rho(\omega) = \frac{4\pi\omega^2}{(2\pi c)^3} \) is the density of states. Integration of Eq. (3) gives two relations between \( n \) and \( j \),

\[
j = -D \frac{\partial n}{\partial r} + \frac{1}{3} \rho L_1,
\]  

(7)

\[
\frac{\partial}{\partial t} \cdot j = D \xi_a^{-2} (\rho f_0 - n) + \rho L_0,
\]  

(8)

where the diffusion constant \( D = \frac{1}{3} c^2 \tau \) and mean free path \( \tau = c \tau \) are determined by the transport scattering rate \( \tau^{-1} = \sum_k w_{kk} (1 - \hat{k} \cdot \hat{k}') \). The absorption length \( \xi_a \) is defined by \( D \xi_a^{-2} = w^+ + w^- \). (An amplifying medium has an imaginary \( \xi_a \) and a negative \( f_0 \) ) In Eq. (7) we have neglected terms of order \( (j / \xi_a)^2 \), which are assumed to be \( \ll 1 \).

Both Eqs. (7) and (8) contain a fluctuating source term. These two terms \( L_0 \) and \( L_1 \) have zero mean and correlators that follow from Eq. (6),

\[
L_0(\omega, r, t) L_0(\omega', r', t') = \Delta' \frac{D}{\rho \xi_a^{-2}} (2f_0 f_0 + f_0 f_0 + f_0 f_0),
\]  

(9a)

\[
L_1(\omega, r, t) L_1(\omega', r', t') = \Delta' \frac{6c}{\rho} f_0(1 + f_0),
\]  

(9b)

where we have abbreviated \( \Delta' = \delta (\omega - \omega') \delta (t - t') \).

Substitution into Eq. (4) gives the correlator

\[
L_0(\omega, r, t) L_1(\omega', r', t') = \Delta' \frac{D}{\rho \xi_a^{-2}} (2f_0 f_1 + f_0 f_1 + f_0 f_1),
\]  

(9c)

where the incident radiation at one end of the waveguide and by the absorbing photodetector at the other end.

To demonstrate how the kinetic theory presented above works in a specific situation we consider the propagation through an absorbing or amplifying disordered waveguide (length \( L \)). The incident radiation is isotropic. All transmitted radiation is absorbed by a photodetector (see Fig. 1). Because of the one dimensionality of the geometry we need to consider only the \( x \) dependence of \( j \) and \( n \) (we assume a unit cross-sectional area). The transmitted photon flux \( I = \int_0^L d\omega \int_0^L d\omega j(\omega, L, t) \) fluctuates around its time-averaged value, \( \bar{I}(t) = T + \delta I(t) \). The (zero-frequency) noise power \( P = \int_0^L dt \delta I(t) \delta I(0) \) is the correlator of the fluctuating flux. We will compute \( P \) by solving the differential equations (7) and (8) with boundary conditions \( n(\omega, 0, t) = n_0(\omega, t), n(\omega, L, t) = 0 \), dictated by the incident radiation at one end of the waveguide and by the absorbing photodetector at the other end.

![FIG. 1. Isotropic radiation (solid arrows) is incident on a waveguide containing an absorbing or amplifying random medium. The transmitted radiation (dashed arrows) is absorbed by a photodetector.](image)
Although we have concentrated here on the waveguide geometries, in order to be able to compare with results in the literature, the calculation of the noise power in the diffusion approximation can be readily generalized to arbitrary geometry. As an example, we give the noise power of the thermal radiation emitted by a sphere (per unit surface area),

\[
\Phi_{th} = \int_0^\infty dw \frac{2D\rho f_{eq}^2}{\xi_a} \sinh^2(s/2) \left[ 8s + 4\cosh s - 7 \sinh s - 4 \sinh(2s) + \sinh(3s) \right],
\]

where \(s = R/\xi_a\) is the ratio of the radius \(R\) of the sphere and the absorption length \(\xi_a\). The mean thermal flux is given by \(\Phi_{th} = \int_0^\infty dw D\rho f_{eq}\xi_a^2(c^2 - 1/s^4)\). The result for \(\Phi_{th}\) could have been obtained from the conventional radiative transfer theory using Kirchhoff’s law, but the result for \(P_{th}\) could not.

\[\frac{\partial}{\partial t} \bar{\rho} + \nabla \cdot (\bar{\rho} \mathbf{v}) = 0,\]

\[\frac{\partial}{\partial t} \mathbf{v} + \nabla \mathbf{v} + \frac{\mathbf{v}}{\tau} = \frac{\nabla p}{\rho},\]

\[\frac{\partial}{\partial t} \mathbf{E} + \nabla \times (\mathbf{v} \times \mathbf{B}) + \mathbf{B} \times \nabla \mathbf{v} + \frac{\nabla \mathbf{E}}{\tau} = -\nabla \mathbf{p} + \mathbf{f}.\]
A dimensionless measure of the magnitude of the photon flux fluctuations is the Mandel parameter \([19]\), \(Q = (P - T)/I\) In a photocount experiment, counting \(n\) photons in a time \(t\) with unit quantum efficiency, the Mandel parameter is obtained from the mean photocount \(\bar{n}\) and the variance \(\text{var} n\) in the long-time limit \(Q = \lim_{t \to \infty} (\text{var} n - \bar{n})/\bar{n}\) We assume a frequency-resolved measurement, so that the integrals over frequency in Eqs (17) and (18) can be omitted The Mandel parameter for thermal radiation from a waveguide and a sphere is plotted in Fig 2, as a function of \(s = L/\xi_a\) for the waveguide and \(s = R/\xi_a\) for the sphere Both cases is at \(\pi\) show both cases in one figure, the \(Q\) for \((\text{corresponding to } /eq 3) = 10^4\) the absorbing medium has been rescaled by a factor of \(10\) to sphere or of the length of the waveguide to the absorption or spontaneous emission from a medium with a complete population inversion Radiation from an absorbing medium and for the amplified spontaneous emission below the laser threshold occurs at \(s = \pi\) \([12]\) Eqs (17) and (18) can be omitted The Mandel parameter diverges in the threshold model for small \(s\), \(Q\) is geometry independent \(\Omega = \frac{2}{15} s^2 f_{eq}\) for \(s \ll 1\) and \(Q = \frac{1}{5} f_{eq}\) for \(s \gg 1\) The Bose-Einstein function \(f_{eq}(\omega, T)\) is to be evaluated at the detection frequency \(\omega\) and temperature \(T\) of the medium The plot in Fig 2 is for \(f_{eq} = 10^{-3}\), typical for optical frequencies at 3000 K

Much larger Mandel parameters can be obtained in amplifying systems, such as a random laser Since complete population inversion corresponds to \(T \to 0^+\), one has \(f_{eq} = -1\) in that case \([12]\) Eqs (17) and (18) apply to amplified spontaneous emission below the laser threshold if one uses an imaginary \(\xi_a\) The absolute value \(|\xi_a|\) is the amplification length, and we denote \(s = L/|\xi_a|\) for the waveguide geometry and \(s = R/|\xi_a|\) for the sphere The laser threshold occurs at \(s = \pi\) in both geometries We have included in Fig 2 the Mandel parameter for these two amplifying systems for the case of complete population inversion Again the result is geometry independent for small \(s\), \(Q = \frac{2}{15} s^2 |f_{eq}|\) for \(s \ll 1\) At the laser threshold \((s = \pi)\) the Mandel parameter diverges in the theory considered here An important extension for future work is to include the nonlinearities that become of crucial importance above the laser threshold The simplicity of the radiative transfer theory developed here makes it a promising tool for the exploration of the nonlinear regime in a random laser

Since radiative transfer theory was originally developed for applications in astrophysics, we imagine that the extension to fluctuations presented here could be useful in that context as well

![Graph of Mandel parameter Q = (P - T)/I vs. s for thermal radiation from an absorbing medium and for the amplified spontaneous emission from a medium with a complete population inversion. The solid curves are for the sphere geometry [Eq (18)], the dashed curves are for the waveguide geometry [Eq (17b)]. The parameter s is the ratio of the radius of the sphere or of the length of the waveguide to the absorption or amplification length. The laser threshold in the amplifying case is at s = π. To show both cases in one figure, the Q for the absorbing medium has been rescaled by a factor of 10⁴ (corresponding to f_{eq} = 10⁻³).](image-url)
