Title: Development of synthetic procedures towards immunostimulating carbohydrates
Issue Date: 2013-12-04
Chapter 5

Synthesis of β-1,3-glucan fragments

Introduction

β-(1,3)-glucans are naturally occurring polysaccharides and were originally identified as essential constituents of the cell wall in fungi and as major storage source in brown seaweed. These glucans are also found on several pathogenic bacteria.\(^1\) The healing and immunostimulating role of these polysaccharides has long been known and β-1,3-glucans have nowadays been identified as Dectin-1 ligands.\(^2\) From a structural point of view these glucans have a linear β-1,3-linked backbone can be substituted in a random fashion with β-1,6-glucosyl branches. A well-known example is Lentinan (Figure 1),\(^3\) which is isolated from Shiitake and Maitake mushrooms and probed as anti-cancer drug. Research towards the elucidation of the immunostimulating properties of these polysaccharides requires sufficient amounts of pure, well-defined oligomers. The availability of a row of β-(1,3)-glucans of variable length can be very valuable to elucidate structure-activity relationships of these polysaccharides.

Several syntheses of β-(1,3)-glucans, both branched and linear, have been reported.\textsuperscript{4,5} To allow access to a library of β-(1,3)-glucans it is desirable to prepare these (functionalized) fragments of oligosaccharides in a more convenient, and possibly automated fashion.\textsuperscript{6} In this Chapter, the solution phase synthesis of a β-1,3-glucan trisaccharide is explored and initial experiments to bring the synthesis to a solid phase synthesis platform are described.

Results & Discussion

Solution phase synthesis of a β-1,3-glucan trisaccharide.

For the synthesis of β-(1,3)-glucan fragments, thioglucoside 4 (Scheme 1) was selected as precursor for the synthesis of the corresponding trifluoro-N-phenylimidate donor (Scheme 2, 9).\textsuperscript{7} The thio-functionality in 4 acts as a temporary masking group for the anomeric hydroxyl group, which in turn can be converted to the trifluoro-N-phenylimidate functionality in 9. For the introduction of β-glycosidic linkages, the participating and sterically demanding C-2-O-pivaloyl (Piv) group was chosen instead of the commonly used benzoyl group. Due to steric bias of the tert-butyl group, possible orthoester formation during the glycosylation is minimized. The use of the benzoyl protective group for the introduction of trans glycosidic linkages can lead to cis-fused product and orthoester formation.\textsuperscript{5b} The 4,6-O-p-chlorobenzylidene diol protective group was described to be more stable than the unsubstituted benzylidene acetal as the electron-withdrawing p-chloro substituent limits susceptibility towards acidic conditions.\textsuperscript{8} The extra stability is desirable in a solid phase synthesis, in which a relatively large amount of strong acid is repetitively used during the glycosylation step. The levulinoyl group serves as a temporary protecting group for the C-3 hydroxyl, which is to be elongated. The synthesis of target thioglucoside started with the introduction of the 4,6-O-chlorobenzylidene acetal. Condensation of glycoside 1 with p-chlorobenzaldehyde and a catalytic amount of p-TsOH in DMF proved to be ineffective under atmospheric pressure at elevated temperature. Performing the reaction under reduced pressure (30 mbar) at 50 °C gave glucoside 2 in 90% yield. Glucoside 2 was converted to a tin acetal by treatment with Bu\textsubscript{2}SnO in refluxing toluene. After cooling down to room temperature, levulinic anhydride was added to the reaction mixture. This resulted in the regioselective introduction of the levulinoyl ester at the C-3 position. According to the conditions described by Ishihara \textit{et al.},\textsuperscript{9} the pivaloyl group was installed with pivalic anhydride and a catalytic amount of Sc(OTf)\textsubscript{3} to give the fully protected glucoside 4 in 81% yield. Unfortunately, this route gave difficulties in scaling up. In particular, the regioselective introduction of the levulinoyl group at the C-3 position could not be achieved on a larger
scale. Therefore, a more robust route in which the para-methoxybenzyl (PBM) group was used for interim protection of the C-3 hydroxyl was employed. First, the free hydroxyl groups in diol 2 were silylated by treatment with TMSCl in pyridine. Then, the C-3 position was regioselectively p-methoxybenzylated using p-anisaldehyde and triethylsilane (TES) in the presence of a catalytic amount of TMSOTf at -86 °C. Finally, addition of TBAF resulted in desilylation of the intermediate and glucoside 5 was isolated in 73% yield. The introduction of the PMB group was successfully accomplished on 51 mmol scale, which shows the robustness of this reaction on big scale. The pivaloyl group was introduced at the C-2 position utilizing pivaloyl chloride and DMAP in refluxing pyridine to give fully protected 6 in 82% yield. The high temperature was required for the installation of the pivaloyl ester, because no conversion was attained at room temperature. The para-methoxybenzyl ether in 6 was cleaved with DDQ in a mixture of DCM and H2O, resulting in glucoside 7. The hydroxyl at the C-3 position was protected with a levulinoyl group using LevOH and DIC in the presence of DMAP, yielding central building block 4.

Reagents and conditions: (a) p-chlorobenzaldehyde, p-TsOH, DMF, 50 °C, 30 mbar, 90%; (b) Bu2SnO, toluene, reflux, then 2.5M Lev2O in THF, 86%/2 steps; (c) Piv2O, Sc(OTf)3, MeCN, 81%; (d) (i) TMSCl, pyridine, 0 °C, (ii) p-anisaldehyde, TES, TMSOTf, DCM, -86 °C, then TBAF, 73%/2 steps; (e) PivCl, DMAP, pyridine, reflux, 82%; (f) DDQ, DCM/H2O, 78%; (g) LevOH, DIC, DMAP, DCM, 90%.

Having thioglycoside 4 in hand, the corresponding trifluoro-N-phenyl imidate donor 9 was prepared (Scheme 2). Donor 9 can be directly activated with triflic acid (TfOH) making this a convenient donor in an automated synthesis. To prepare donor 9 from thioglycoside 4 the anomic thiotoluyl group is to be hydrolyzed. The presence of the acid-labile chlorobenzylidene protective group in donor 4 required an anhydrous method. Therefore, glucoside 4 was treated with a combination of NIS and TFA to provide the intermediate anomic trifluoroacetate 4a.

Reagents and conditions: (a) NIS, TFA, DCM, 0 °C; (b) piperidine, 85%; (c) ClC(=NPh)CF3, DBU, acetone, 0 °C, 94%.
NMR spectroscopy revealed the anomeric trifluoroacetate to be the β anomer only \((J_{1,2} = 7.8\) Hz). In the \(^1H\) NMR spectrum of 4a a smaller set of signals was also observed, corresponding to pivaloyl-migration product 4b (Figure 2, \(J_{1,2} = 3.6\) Hz, \(~15\%\)).\(^{12}\) Cleavage of the anomeric trifluoroacetate group with piperidine led to hemiacetal 8. The corresponding trifluoro-\(N\)phenyl imidate donor 9 was obtained by treatment of 8 with \(N\)-phenyl trifluoroacetimidoyl chloride\(^{13}\) and DBU in acetone.

**Figure 2.** Part of the \(^1H\) NMR spectrum of glucoside 4 after treatment with NIS/TFA in DCM-\(d_2\) at 0 °C.

With glucosyl donor 9 in hand, its glycosylating properties were studied by the solution phase synthesis of a trimeric β-1,3-glucan fragment (Scheme 3). Allyl alcohol was selected as the first acceptor to obtain the same allyl glucoside product as produced by executing an automated synthesis using the 1,4-butenediol linker. Glucosyl donor 9 was reacted with allyl alcohol and TfOH (cat.) yielding allyl glucoside 10 in 70% yield. The temporary levulinoyl group was removed with hydrazine hydrate in a mixture of pyridine and acetic acid giving glucosyl acceptor 11 in 96%. Next, donor 9 and acceptor 11 were coupled with a catalytic amount of TfOH in DCM, which led to the isolation of disaccharide 12 in 99% yield. Subsequent delevulinylation of the disaccharide afforded disaccharide acceptor 13, which was glycosylated with donor 9 to give trisaccharide 14 in 80% yield.

**Scheme 3.** Synthesis of trisaccharide 14.

Reagents and conditions: (a) Allyl alcohol, TfOH, DCM, 0 °C, 70%; (b) hydrazine hydrate, pyridine/AcOH, 11: 96%, 13: 94%; (c) TfOH, DCM, 0 °C, 12: 99%, 14: 80%.
NMR analysis of the trisaccharide revealed several remarkable features. First, the anomeric proton of the middle glucoside showed a very small coupling constant ($J_{\alpha,\beta} = 2.1$ Hz), which is unexpected for a $\beta$-glucosyl linkage in a $\mathrm{C}_1$ conformation. This small coupling was not observed in the NMR analysis of the disaccharide precursor. Also, the H-2’ signal of the middle residue was not split into the expected triplet. Instead, a broad singlet was observed. H-H COSY NMR showed only a weak correlation between H-2’ and H-3’. Furthermore, TOCSY NMR analysis showed two distinct spin systems in the middle glucoside: a spin system between H-1’ and H-2’ and a spin system of H-3’ through H-6’, indicating that the middle glucoside does not adopt the expected $\mathrm{C}_1$ chair conformation. Another noteworthy observation is the shift of the benzylidene proton of the middle glucoside. This proton is about 1 ppm upfield compared to the other two benzylidene signals, which suggests a high degree of electron shielding. These results are in line with structural effects reported for 4,6-O-benzylidinated $\beta$-1,3-glucans. Vetvicka and coworkers$^{14}$ performed a series of NOESY NMR experiments, which suggest that the affected glucosides uptake a pseudorotational itinerary between the $\mathrm{C}_1$ and $\mathrm{B}$ or $\mathrm{B}_2$ conformation rather than the $\mathrm{C}_1$ chair which is the unaffected glucoside residue. The crystal structure of a 4,6-O-benzylidene protected hexasaccharide reported by Ensley et al.$^4$ confirmed that glucoside residues in between (third and fifth) adopt a twist boat conformation whereas all other units were found in a $\mathrm{C}_1$ conformation.

Taken together, the above described results show that the trifluoro-N-phenyl imidate donor 9 is a suitable donor for the construction of the $\beta$-1,3-glycosidic linkages. The 4,6-O-chlorobenzylidene functionality remains intact during the glycosylations and the C-2-pivaloyl ester ensures stereoselective couplings. Encouraged by the successful solution phase synthesis of trisaccharide 14, the solution phase chemistry was translated to an automated solid phase format.

**Automated synthesis of $\beta$-1,3-glucan fragments.**

The automated synthesis of a tetrameric $\beta$-glucan fragment$^{15}$ was explored using the above described donor 9 and 1,4-butene-diol linker 15 (Scheme 4).$^{16}$ This linker is stable towards the reaction conditions applied and the product can be cleaved via a cross metathesis reaction with ethene and Grubbs first-generation catalyst at the end of the synthesis.$^{17}$ Donor 9 was used in excess (3 eq. per coupling cycle) and since the glycosylation proceeded fast in solution phase, a short coupling time (3x 15 minutes) was employed. The amount of triflic acid (0 °C and 0.1 eq. per donor, respectively) and the temperature were not changed with respect to the solution phase synthesis. The temporary levulinoyl group was cleaved at 40 °C to ensure rapid and complete unmasking of the C-3-hydroxyl.
Scheme 4. Automated synthesis of tetrasaccharide 16.

Reagents and conditions: (a) Donor 9 (3 eq.), TfOH (0.3 eq.), 0 °C, 15 min.; (b) hydrazine acetate (10 eq.), pyridine/AcOH, 40 °C, 10 min.; (c) Grubbs first-generation catalyst, ethene, DCM, overnight, 44%.

After cleavage from the resin and filtration over a plug of silica, LC-MS analysis showed the predominant formation of tetrasaccharide 16, along with presence of a minor amount trisaccharide 16a (tetramer: trimer, ~26:1) and trace amounts of disaccharide (Figure 3). Preparative HPLC was employed to isolate tetrasaccharide 16 in 44% yield (~91% yield/step). In an attempt to further improve the efficiency of the synthesis of tetrasaccharide 16, the couplings were performed at 20 °C. LC-MS analysis of the so-obtained product however revealed a higher proportion of trisaccharide relative to the tetrasaccharide. Therefore, the glycosylation temperature was set to 0 °C for further syntheses. Although the automated preparation of the tetrameric β-1,3-glucan fragment was successful, deprotection of the pivaloyl esters turned out to be troublesome. Treatment with bases such as ammonia and KOH did not result in deprotection of the C-2 position. Therefore, a pivaloyl-like group that can be cleaved in a milder and faster fashion was investigated.

Figure 3. LC-MS chromatograms of the crude tetrasaccharide after cleavage from the resin (A, C4 column, linear gradient 70 → 90% B) and after HPLC purification (B).
Synthesis of β-1,3-glucan fragments with the AzDMB-protective group.

To circumvent the troublesome deprotection of the pivaloyl group the recently reported 4-azido-2,2-dimethyl-butanoic acid (AzDMB) protective group (Scheme 5) was implemented. The appended azido functionality allows the cleavage of the ester by a Staudinger reduction reaction or hydrogenation. The synthesis of the glucosyl donor 21 starts with diol 2 which was regioselectively 2-methylnaphthylated at the C-3 position. This was achieved by first preparation of the tin ketal followed by treatment with 2-naphthylmethyl bromide and CsF in DMF to yield alcohol 17 in 69% yield. Subsequent treatment of 17 with freshly prepared AzDMBCl in pyridine gave fully protected glucoside 17a. Because this product could not be separated from 4-azido-2,2-dimethyl-butanoic acid, the crude product was subjected to a mixture of DDQ in DCM/H$_2$O to give glucoside 18 in 78% yield over 2 steps. The free hydroxyl was protected with a levulinoyl group to give fully protected glucoside 19 in 90% yield. Thio-donor 19 was transformed into imidate 21 using the same sequence of reactions, as described for the synthesis of pivaloyl-donor 9 from hemiacetal 4.

Reagents and conditions: (a) (i) Bu$_2$SnO, toluene, reflux, (ii) 2-NAP-Br, CsF, DMF, overnight, 69%/2 steps; (b) (i) AzDMBCl, pyridine, 110 °C, (ii) DDQ, DCM/H$_2$O, 78%/2 steps; (c) LevOH, DIC, DMAP, DCM, 90%; (d) NIS, TFA, DCM, 0 °C, then piperidine, 86%; (e) ClC(=NPh)CF$_3$, Cs$_2$CO$_3$, acetone, 96%.

The AzDMB protected donor 21 was explored in the solid phase synthesis of trisaccharide 25 (Scheme 6). The tandem RCM cleavable linker 22, described in Chapter 4, was applied. Since the coupling (3x 3 eq. of donor, 3x 0.1 eq. of TfOH) and deblocking conditions (3x 6.7 eq. of hydrazine hydrate) described above were shown to be effective, the same conditions were applied. Before cleaving the product from the resin the AzDMB groups were removed off-resin by Staudinger reduction of the azides with tributylphosphine in the presence of aqueous KOH. Some optimization was required because the hydrophobic polystyrene resin significantly shrinks in aqueous solutions, making the azides on the resin inaccessible for the reagents. Using a mixture of 0.5M aqueous KOH in dioxane (1/19, v/v) and 9 eq. of tributylphosphine at elevated temperature (50 °C) led to the desired triple deprotection and set the stage to release the trisaccharide from the resin by tandem RCM. The resin was treated with Grubbs second-generation catalyst for 2 hours, after which the trisaccharide was isolated. LC-MS analysis of the crude product showed that the whole synthetic procedure had proceeded uneventfully and no benzylidene cleavage products or diastereomers resulting from non-selective glycosylation reactions could be observed. After purification of the trisaccharide over a small plug of silica the target trisaccharide 24 was isolated in 36% yield (~88% per
step). Cleavage of the p-chlorobenzylidene functions was readily accomplished by hydrogenolysis in a THF/H₂O/tert-BuOH solvent mixture to provide β-glucan trisaccharide 25 in 91% yield.

**Scheme 6.** Solid phase synthesis of a trisaccharide β-1,3-glucan fragment.

Reagents and conditions: (a) Donor 21 (3 eq.), TfOH (0.3 eq.), DCM, 0 °C, 15 min.; (b) hydrazine hydrate (6.7 eq.), pyridine/AcOH, 40 °C, 10 min.; (c) Bu₃P (9 eq.), dioxane/0.5M KOH, 50 °C, 90 min.; (d) Grubbs second-generation catalyst (0.12 eq.), DCM, 2 h., 36%/8 steps; (e) H₂, Pd/C, THF/H₂O/tert-BuOH, 2 h., 91%.

**Conclusions**

The successful solution phase synthesis of a β-(1,3)-glucan trisaccharide formed the basis for the automated solid synthesis of a partly protected tetrameric β-(1→3)-glucan fragment. However, cleavage of the pivaloyl esters in this tetrasaccharide turned out to be troublesome and did not give the fully unprotected targets. Replacement of the pivaloyl by the mildly cleavable AzDMB protective group led to the first successful solid phase synthesis of a β-(1,3)-glucan trisaccharide fragment. Having established the glycosylation properties and deprotection conditions, the (automated) solid phase synthesis of larger β-(1,3)-glucan fragments can now be explored.

**Experimental section**

**General experimental procedures.** Chemical shifts (δ) are given in ppm relative to TMS as internal standard. All ¹³C APT NMR spectra are proton decoupled. Reactions were performed at rT unless stated otherwise and were followed by TLC analysis with detection by UV-absorption (254 nm) where applicable and by spraying with 20% sulphuric acid in EtOH or with a solution of (NH₄)₆Mo₇O₄ₓ·H₂O (25 g L⁻¹), followed by charring at 150 °C. Flash column chromatography was performed on silica gel (0.04-0.063 nm) and size exclusion chromatography (SEC) was performed on Sephadex™ LH-20. Experiments that required an inert atmosphere were carried out under dry argon. Dichloromethane
(p.a.) was distilled over P₂O₅ prior to use. Molecular sieves (3Å) were flame-dried before use. LC-MS analysis was performed using a C4 column with the following solvent systems: A = 100% water, B = 100% acetonitrile, C = 1% TFA.

**General experimental procedures for (automated) solid phase synthesis.** The synthesizer used was supplied by Ancora Pharmaceuticals. The synthesizer’s solvent bottles are filled with commercially acquired solvents, which are pre-dried 24 h. before use on 4Å molecular sieves. The solutions containing building block, activator and deblocking reagents are freshly prepared directly before use with pre-dried solvents. During the synthesis of trisaccharide 24, the coupling, deblocking, and reduction reagents were added manually.

**Reagent solutions:**
- **Building block:** Donor 9 or 21 in DCM (0.09M)
- **Activator:** Trifluoromethanesulfonic acid in DCM (0.09M)
- **Deblocking:** Synthesis of tetramer 16: Hydrazine acetate in pyridine/AcOH (4/1, v/v, 0.12M)
  - Synthesis of trisaccharide 24: Hydrazine hydrate in pyridine/AcOH (4/1, v/v, 0.12M)
- **Reduction:** Bu₃P in THF dioxane/0.5M KOH (19/1, v/v, 0.25M)

**Protocol A: Agitation of the resin during washing.** After addition of the appropriate solvent (2-4 mL), a gas-flow is applied from the bottom of the reaction vessel (RV) for 15 seconds to agitate the resin suspension. Then the RV is emptied.

**Protocol B: Agitation of the resin during reaction.** After addition of the appropriate solvent (2-4 mL), a gas-flow is applied from the bottom of the RV for 10 seconds to agitate the resin suspension. Then the purging is halted and the suspension is allowed to settle for 20 sec.

**Protocol C: Swelling of new resin.** The RV is charged with dry resin. The resin is washed with DCM (3x), alternating THF and hexane (3x), THF (1x) and DCM (3x). Every wash step involves protocol A.

**Protocol D: Washing of the resin before or after the reaction.** If applicable, the chiller temperature is set to ambient. The pre-swollen resin is washed with alternating THF and hexane (3x), followed by THF (1x) and DCM (3x). Every wash step involves protocol A.

**Protocol E: Coupling cycle.** The resin is washed with DCM (3x) before the building block solution (1.5 mL, 0.09M) is added. Then, the temperature is set to -5 °C to ensure an actual temperature of 0 °C in the RV. Simultaneously a pause of 10 min is started. When the temperature of the chiller has reached its target point, the activator solution (300 µL for the synthesis of tetrasaccharide 15, 150 µL for the synthesis of trisaccharide 24) is added. Protocol B is applied for 15 min. Then the RV is emptied and the solution is collected in a mixture of DCM/H₂O/triethylamine (50/5/1, v/v/v). The resin is washed with DCM (3x) and the solutes are similarly collected.

**Protocol F: Deblocking.** The resin is washed with DMF (3x) before the deblock solution (2.5 mL, 0.12M) is added. The temperature was raised to 40 °C and the resin was agitated using protocol B for 10 min. Then the RV is emptied and the resin is washed with DMF (3x).

**Protocol G: Washing of the resin after deblocking.** The temperature of the chiller is set to ambient. The resin is successively washed with DMF (3x), DCM (3x), alternating THF and hexane (6x), 0.01M AcOH in THF (6x) and THF (3x). Every wash step involves protocol A.

**Protocol H: Reduction.** The resin is washed with THF (3x) before the reduction solution is added (2.13 mL) and the resin is agitated using protocol B for 90 min. while the temperature is raised to 50 °C. Then the RV is emptied and the resin is washed with DMF (6x) and THF (6x).
Protocol I: Washing of the resin after reduction. The temperature of the chiller is set to ambient. The resin is successively washed with DMF (6x), DCM (3x), alternating THF and hexane (6x), 0.01M AcOH in THF (6x) and THF (3x). Every wash step involves protocol A.

Protocol J: Suspending of the resin for isolation. The resin is washed with alternating DCM and MeOH (2x), followed by a mixture of DCM/MeOH (7/1, v/v, 2x), both employing protocol A. Then a mixture of DCM/MeOH (7/1, v/v) is added, the resin is agitated for 15 sec. after which time the gas-flow was halted and the program was paused. The suspended resin is isolated and this last procedure is repeated two times.

\[ p\text{-Tolyl} \ 4,6-O-(p\text{-chlorobenzylidene})-1\text{-thio}-\beta\text{-D-glucopyranoside (2)} \]: To a solution of thioglucoside 1 (20 g, 69.8 mmol) in DMF (0.6 M, 120 mL) was added p-chlorobenzaldehyde (210 mmol, 29.4 g, 3 eq.) and a catalytic amount of p-toluenesulfonic acid. The mixture was stirred on a rotary evaporator (50 °C, 30 mbar) for 3.5 hours. The reaction was quenched with TEA until pH ~7. The mixture was concentrated in vacuo, co-evaporated with toluene and crystallized from EtOAc/PE to give the title compound in 90% yield (62.9 mmol, 25.7 g). Melting point: 188 °C. [\( \delta \text{H} \): -44.4 (c = 1, MeCN). **p-Tolyl 4,6-O-(p-chlorobenzylidene)-3-O-(methoxybenzyl)-1-thio-β-D-glucopyranoside (5):** To a stirred solution of glucoside 2 (25.0 g, 51.5 mmol) in pyridine (100 mL, 0.5M) was added TMSCl (19.5 mL, 153.5 mmol, 3.0 eq.) at 0 °C. The mixture was gradually warmed to room temperature, and after TLC analysis (DCM/acetone, 19/1, v/v) indicated complete conversion of the starting material, the mixture was diluted in EtOAc and washed with H₂O (2x). The combined aqeous phases were extracted with EtOAc (2x). The combined organics were dried over MgSO₄, filtered, and concentrated in vacuo. The crude compound was evaporated with toluene. The silyl ether was dissolved in DCM (350 mL, 0.15M), p-anisaldehyde (7.0 mL, 11.3 mmol, 1.1 eq.) was added and the mixture was cooled to -86 °C. Added was Et₃SiH (1.8 mL, 56.5 mmol, 1.1 eq.) and TMSOTf (0.8 mL, 4.5 mmol, 0.09 eq.) and the mixture was stirred at -86 °C overnight, after which TLC analysis (PE/EtOAc, 3/1, v/v) indicated complete conversion of the starting material. The mixture was quenched with MeOH and NaOMe (up to pH ~ 9) and the mixture was warmed to room temperature. The mixture was diluted with DCM, washed with sat. aq. NaHCO₃. The aqueous phase was extracted with DCM (2x). The combined organics were dried over MgSO₄, filtered, and concentrated in vacuo. The crude compound was treated with TBAF (1M solution in THF, 55 mL, 55 mmol, 1.07 eq.) and stirred at room temperature until TLC analysis (PE/EtOAc, 3/1, v/v) indicated complete conversion. The reaction mixture was diluted with DCM and washed with sat. aq. NaHCO₃. The aqueous phase was extracted with DCM (2x). The combined organics were dried over MgSO₄, filtered, and concentrated in vacuo. Crystallization from hot EtOH gave the product as a white solid in 73% yield (23.8 g, 37.6 mmol). Melting point: 163 °C. [α]D: -46.6 (c = 1, DCM). IR (neat, cm⁻¹): 3487, 2953, 2920, 2882, 2862, 1614, 1603, 1514, 1491, 1466, 1400, 1379, 1348, 1304, 1250, 1227, 1171,

*p-Tolyl 4,6-O-(p-chlorobenzylidene)-3-O-(naphthalen-2-methyl)-1-thio-β-D-glucopyranoside (17): Glucoside 2 (7.0 g, 25.7 mmol) was suspended in toluene (64 mL, 0.4M) followed by addition of Bu4SnO (6.40 g, 25.7 mmol, 1 eq.). The reaction mixture was heated to reflux and stirred for 2 h. The reaction mixture was cooled to rT, concentrated, and co-concentrated with toluene. The obtained white solid was dissolved in DMF (86 mL, 0.3M) followed by addition of 2-(bromomethyl)naphthalene (6.85 g, 30.9 mmol, 1.2 eq.) and CsF (5.08 g, 33.4 mmol, 1.3 eq.). The reaction mixture was stirred overnight. A white suspension was obtained. The reaction mixture was diluted with EtOAc, washed with H2O, brine, dried over MgSO4, filtered, and concentrated. A white solid was obtained, which was recrystallized from EtOH. The title compound was obtained as a white powder in 69% yield over 2 steps (9.7 g, 17.63 mmol). Melting point: 172 °C. [α]D20 -33 (c = 1, DCM). IR (neat, cm⁻¹): 3300, 2912, 1367, 1265, 1107, 1085, 1008, 810, 734, 705, 611. ¹H NMR (300 MHz, CDCl3, HH-COSY, HSQC): 7.92-7.63 (m, 4H, H arom), 7.53-7.34 (m, 9H, H arom), 7.12 (d, 2H, J = 8.1 Hz, H arom), 5.52 (s, 1H, CH chlorobenzylidene), 5.03 (d, 1H, J = 12.0 Hz, CHH naphthylmethyl), 4.96 (d, 1H, J = 12.0 Hz, CHH naphthylmethyl), 4.55 (d, 1H, J = 9.6 Hz, H-1), 4.36 (dd, 1H, J = 10.5 Hz, J = 4.8 Hz, H-6a), 3.79-3.42 (m, 3H, H-6b, H-2, H-3, H-4, H-5), 2.57 (d, 1H, J = 2.8 Hz, C-2-OH), 2.34 (s, 3H, CH3 Stol). ¹³CAPT NMR (100 MHz, CDCl3, HH-COSY, HSQC): 135.7 (Cq arom), 133.8 (CH2 arom), 129.8 (CH2 arom), 128.4 (Cq arom), 128.2-125.9 (CH2 arom), 100.6 (CH benzylidene), 88.8 (C-1), 81.4 (C-3 or C-4), 80.9 (C-3 or C-4), 74.8 (CH2 naphthylmethyl), 72.4 (C-2), 70.6 (C-5), 68.6 (C-6), 21.2 (CH3 Stol). *p-Tolyl 4,6-O-(p-chlorobenzylidene)-2-O-(4-azido-2,2-dimethylbutanoyl)-1-thio-β-D-glucopyranoside (18): 4-Azido-2,2-dimethylbutanoic acid (1.90 g, 12.14 mmol, 2 eq. relative to glucoside) was dissolved in DCM (30.4 mL, 0.4M)
followed by addition of oxaly chloride (2.60 mL, 30.4 mmol, 2.5 eq. relative to 4-Azido-2,2-dimethylbutanoic acid). The reaction mixture was heated to reflux and stirred for 1 h. The reaction mixture was concentrated and co-evaporated with toluene (2x) and chloroform (1x). The obtained acid chloride was dissolved in pyridine (30.4 mL, 0.2M) and cooled to 0 °C, followed by slow addition of glucoside 17 (3.25 g, 6.07 mmol). The reaction mixture was heated to 110 °C and the reaction mixture was stirred overnight. TLC analysis (hexane/ EtOAc: 3/1, v/v) showed total conversion into a higher running spot (hexane/EtOAc: 3/1, v/v, Rf 0.81) and the reaction mixture was cooled to rT, concentrated in vacuo and co-concentrated with toluene (2x). The obtained yellowish oil (crude 17a) was dissolved in a DCM/H2O mixture (9/1, 91.1 mL, 0.1M) and the resulting mixture was cooled to 0 °C. DDQ (3.10 g, 13.67 mmol, 1.5 eq.) was added and the reaction mixture was allowed to warm to rT. After 1 h., TLC analysis showed total conversion into a lower running spot (hexane/EtOAc: 3/1, Rf 0.75). The reaction mixture was quench by addition of Na2SO3 (aq., sat.), diluted with DCM, followed by separation of the layers. The organic layer was washed with brine, dried over MgSO4, filtered, and concentrated. A yellow oil was obtained. Column chromatography (pentane/EtOAc: 1/0 → 7/3) gave the title compound as a colorless oil, which crystallized on standing. Glucoside 18 was obtained in 78% yield over 2 steps (3.20 g, 4.75 mmol). [a]D: -34 (c = 1, DCM). IR (neat, cm⁻¹): 2926, 2096, 1737, 1263, 1089, 813, 731, 702, 665. 1H NMR (400 MHz, CDCl3, HH-COSY, HSQC): 7.40-7.24 (m, 6H, H-arom), 7.13-7.11 (m, 2H, H-arom), 5.49 (s, 1H, CHPh chlorobenzylidene), 4.92 (t, 1H, J = 10.0 Hz, H-2), 4.76 (d, 1H, J = 10.0 Hz, H-1), 4.32 (dd, 1H, J = 10.8 Hz, H = 5.2 Hz, H-6a), 3.89 (t, 1H, J = 9.6 Hz, H-3), 3.73 (t, 1H, J = 10.4 Hz, H-6b), 3.51 (t, 1H, J = 9.6 Hz, H-4), 3.45-3.36 (m, 3H, H-5, CH2 AzDMB), 3.14 (bs, 1H, OHJ), 2.33 (s, 3H, CH3 STol), 2.00-1.80 (m, 2H, CH2 AzDMB), 1.27 (s, 3H, CH3 AzDMB), 1.23 (s, 3H, CH3 AzDMB). 13C APT NMR (100 MHz, CDCl3, HH-COSY, HSQC): 175.6 (C=O), 138.4 (Cq AzDMB), 135.3-134.8 (Cq arom), 133.0 (Cq arom), 129.7-128.3 (CH-arom), 128.2 (Cq arom), 128.2-127.7 (CH-arom), 100.8 (CQPh chlorobenzylidene), 86.8 (C-1), 80.2 (C-4), 73.3 (C-3), 72.2 (C-2), 70.1 (C-5), 68.2 (C-6), 47.8 (CH2 AzDMB), 40.9 (Cq AzDMB), 38.7 (CH2 AzDMB), 25.6 (CH2 AzDMB), 24.6 (CH3 AzDMB), 21.0 (CH3 STol). 4,6-[(p-chlorobenzylidene)-2-O-(4-azido-2,2-dimethylbutanoloyl)-3-O-
levulinyl-α/β-n-glucopyranoside (20): Glucoside 19 (372 mg, 0.60 mmol) was
dissolved in freshly distilled DCM (3 mL, 0.2M) and the reaction mixture was
stirred under argon and cooled to 0 °C. NIS (148 mg, 0.66 mmol, 1.1 eq.) and TFA (51 µL, 0.66
mmol, 1.1 eq.) were added. TLC analysis (PE/EtOAc: 12/8, v/v) did not show any Rf difference but
an UV positive spot (indicating p-thiocresol being formed) was observed. After 1 h., the reaction
mixture was cooled to 0 °C, followed by piperidine (178 µL, 1.80 mmol, 3 eq.). After 30 min., TLC
analysis showed total conversion of the anomeric trifluoroacetate into a lower running spot
(PE/EtOAc: 12/8, v/v, Rf 0.41). The reaction mixture was quenched by subsequent addition of
triethylamine (reaction mixture turned from dark purple to yellow) and Na2SO3 (aq, sat) (yellow
reaction mixture turned colorless). The reaction mixture was diluted with DCM, washed with H2O,
dried over MgSO4, filtered, and concentrated. Column chromatography (PE/EtOAc: 1/0 ➔ 4/6) gave
hemiacetal 20 as an anomeric mixture (α/β: 1/0.6) and a colourless oil in 86% yield (278 mg, 0.51
mmol). IR (neat, cm⁻¹): 2096, 1720, 1419, 1365, 1265, 1089, 1014, 815, 732, 702. 1H NMR (400 MHz,

**Cyclopentenyl 4,6-O-(p-chlorobenzylidene)-3-O-[[4,6-O-(p-chlorobenzylidene)-3-O-[[4,6-O-(p-chlorobenzylidene)-β-D-glucopyranosyl]]-β-D-glucopyranosyl]-β-D-glucopyranoside (24):** The resin was washed with dry DCM (8x), suspended in DCM (4.5 mL, 0.01M) and purged with argon. Grubbs second-generation catalyst (~3 mg) was added and the resulting brown suspension was allowed to stand at rt for 2 h. The solution was filtered off and the resin was washed with DCM and MeOH. The filtrates were concentrated and the obtained residue was filtered over a plug of silica (DCM/MeOH, 99/1, v/v) and concentrated. The title compound was isolated as a white solid in 36% yield over 8 steps (15 mg, 16 µmol). [α]D: -6.0 (c = 0.1, ACN).

IR (neat, cm⁻¹): 2924, 2854, 1421, 1379, 1265, 1172, 1074, 1014, 915, 732, 702, 621. ¹H NMR (400 MHz, CDCl₃, HH-COSY, HSQC): 7.43 (d, 6H, J = 8.0 Hz, H arom), 7.34 (d, 6H, J = 8.4 Hz, H arom), 5.71-5.69 (m, 1H, H-3 cyclopentenyl), 5.53 (s, 2H, 2x CHPh chlorobenzylidene), 5.50 (s, 1H, CHPh chlorobenzylidene), 4.65-4.57 (m, 3H, H-1 cyclopentenyl, 2x H-1), 4.50 (d, 1H, J = 8.0 Hz, H-1), 3.35 (dd, 1H, J = 10.8 Hz, J = 6.0 Hz, H-6a), 4.29-4.24 (m, 2H, 2x H-6a), 3.81-3.75 (m, 7H, 3x H-6b, 3x H-3, H-2), 3.69-3.54 (m, 5H, 2x H-2, 3x H-4), 3.49-3.38 (m, 3H, 3x H-5), 2.70-2.58 (m, 2H, 2x H-2 cyclopentenyl), 2.55-2.47 (m, 2H, 2x H-2 cyclopentenyl).

¹³C APT NMR (100 MHz, CDCl₃, HH-COSY, HSQC): 135.5-135.0 (C₉ arom), 130.9-127.4 (C₁₃ arom, 3-cyclopentenyl), 105.6 (C-1), 105.5 (C-1), 101.8 (C-1), 101.1 (C₉ Ph chlorobenzylidene), 100.3 (C₉ Ph chlorobenzylidene), 100.2 (CHPh chlorobenzylidene), 84.5, 83.5, 80.1, 78.7, 78.6, 75.2, 74.5, 73.9, 73.2 (3x C-2, 3x C-3, 3x C-4), 79.0 (C-1 cyclopentenyl), 68.5 (2x C-6), 68.3 (C-6), 66.9 (C-5), 66.8 (C-5), 66.6 (C-5), 40.2 (C-2 cyclopentenyl), 39.4 (C-2 cyclopentenyl). HRMS: [M+Na]⁺ calef for C₃₀H₂₄Cl₁F₅Na₂O₆Na: 959.18219, found 959.18249.

**Cyclopentenyl 3-O-[[3-O-[[β-D-glucopyranosyl]]-β-D-glucopyranosyl]-β-D-glucopyranoside (25):** Trisaccharide 24 (9 mg, 9.59 µmol) was dissolved in a mixture of THF/H₂O/tert-BuOH (2/1/1, v/v/v, 1 mL, 0.01M). The reaction mixture was purged with argon followed by addition of Pd/C (cat.). After stirring under argon for 15 min., the reaction mixture was purged with H₂ (g) and stirred for 2 h. TLC analysis showed total conversion into a single lower running spot (DCM/MeOH, 3/1, v/v, Rₚ 0.2). The reaction mixture was filtered over a Whatmann filter, washed with H₂O, neutralized with ammonia, and concentrated. The obtained residue was subjected to gel filtration (HW-40, 0.15M NH₄OAc in H₂O) and subsequent lyophilization. The deprotected trimer was obtained as a fine white powder in 91% yield (5.0 mg, 8.7 µmol). ¹H NMR (600 MHz, 284 K, D₂O, HH-COSY, HSQC): 4.74 (d, 1H, J = 8.4 Hz, H-1), 4.72 (d, 1H, J = 7.8 Hz, H-1), 4.50 (d, 1H, J = 8.4 Hz, H-1), 4.42-4.40 (m, 1H, H-1 cyclopentenyl), 3.90-3.87 (m, 2H, 2x H-6a), 3.75-3.66 (m, 5H, 3x H-6b, H-3, H-4), 3.52-3.38 (m, 9H, 2x H-2, 2x H-4, 2x H-3, 3x H-5), 3.31 (t, 1H, J = 7.8 Hz, H-2), 1.86-1.52 (m, 8H, 4x H-2 cyclopentenyl, 2x H-3 cyclopentenyl). ¹³C NMR (150 MHz, 284 K, D₂O, HH-COSY, HSQC): 103.8 (C-1), 103.5 (C-1), 101.6 (C-1), 85.0 (C-3 or C-4), 84.9 (C-3 or C-4), 83.4 (C-1 cyclopentenyl), 77.0, 76.6, 76.5, 76.4, 74.0, 70.5, 69.1, 69.1 (C-2, 2x C-3, 3x C-4, 3x C-5),
Synthesis of $\beta$-1,3-glucan fragments
